**Key words:** Broiler, caecectomized, intact cockerels, oilseed meal, canola, soyabean

**Abstract:** The experiment was conducted to determine metabolizable energy and amino acid digestibilities of the soybean, sunflower and canola meals using broiler chickens by collection digesta from the terminal ileum and excreta using titanium oxide (indigestible marker) in intact and caecectomized cockerels. The mean excreta apparent and true digestibility of amino acid in broiler and intact cockerel for soybean meal were 76.99, 78.07, 84.18 and 88.35 sunflower meal: 92.16, 92.84, 78.09 and 85.94 and canola meal 69.82, 70.22, 86.47 and 88.50%, respectively. The mean values of ileum apparent and true digestibilities (Standardized Ileal digestibility) of amino acid in broiler for soybean meal were 72.18 and 73.12; sunflower meal: 47.48 and 48.47 and canola meal: 62.05 and 62.45%, respectively. The average apparent and true digestibilities of amino acid in caecectomized cockerel and broiler in soybean meal were 80.34 and 84.45 sunflower meal 74.48 and 82.47 and canola meal 84.74 and 87.12%, respectively. Apparent digestibility of amino acid in soybean, sunflower and canola meals measured in broiler (excreta and ileum) were 9-11, 34-50 and 19-27% units lower than those measured in intact and caecectomized cockerel. The AME, AMEn, TME and TMEn values for canola and sunflower meals obtained at 21 and 42 days broiler age were significantly higher than cockerels. Intact cockerels obtained higher metabolizable energy from canola and sunflower meals than those broiler excreta or ileum and caecectomized cockerels.

## INTRODUCTION

A number of factors influence the metabolizable energy and amino acid digestibility of oilseed meals. A number of studies have demonstrated that the amino acid digestibility and metabolizable energy of feed ingredients may depend upon the age, genotype and gender of the

bird. Difficulties associated with amino acid bioassay can be a major source of variation which is often overlooked (Ravindran and Bryden, 1999). A number of studies have examined this factor using broilers of different ages, laying hens and roosters fed different cereals and protein meals (Wallis and Balnave, 1984a, b; Rostagno *et al.*, 1995; Batal and Parsons, 2002a, b; Huang *et al.*, 2005,

2006, 2007; Garcia *et al.*, 2007). In general, the digestibility coefficient of amino acids increases with age and varies with feedstuff.

Digestibility assay may be separated into two main categories: excreta and ileal. Excreta digestibility involves the collection of excreta from intact or cecectomized birds. For measurement of ileal digestibility digesta are collected from the digesta part of the ileum. Most of the published data on digestible amino acids in feed ingredients have been obtained from excreta assays with roosters (Green *et al.*, 1987; Parsons, 1991; NRC., 1994; Rhone-Poulenc, 1993). Although, evidence suggests that ileal digestibility values are better indicators of amino acid availability than excreta-based values (Ravindran *et al.*, 1999) there is a paucity of data on the ileal digestibility values (Ravindran *et al.*, 2005). The caecal microflora may change the profile of amino acid during flow of digesta through this part of the gastro intestinal tract. Because the caeca are the main sites of post ileal microflora activity, caeectomy has been proposed as a method for reducing microbial influence on digestibility (Parsons, 1984; Johns *et al.*, 1986; Parsons, 1986; Green *et al.*, 1987; Green, 1988).

Variation in digestibility values will also arise from difficulties associated with the conduct of bioassay procedures and the measurement of Endogenous Amino Acid Losses (EAAL) and Endogenous Energy Losses (EEL). Endogenous amino acid at the ileal level can be divided into a basal EAAL fraction assumed to be independent of the raw material and to be occur in any diet and a specific fraction with is considered a characteristic of the single raw material. Standardized ileal digestibility is an approach to describe amino acid digestibility for broiler. Golian reported that using the NFD methods which is relatively simply, may allow feed ingredients to be compared more accurately, thus leading to a greater consistency in feed evaluation. Ravindran and Hendriks shown that amino acid profile of endogenous amino acids losses did not differ between broiler, layer and adult rooster except for serine, glutamic acid, proline and isoleucine.

Song *et al.* (2003) reported that differences in endogenous amino acid excretion using the N-free and fasting methods. However, the true available amino acids were higher for the N-free methods than for the fasting methods.

The main objective of the present study was to compare estimates of amino acid digestibility and metabolizable energy determined using differences bioassay and age on the excreta and ileal digesta in broiler chickens and intact and cecectomized cockerel of soybean, canola and sunflower meal.

## MATERIALS AND METHODS

To compare the amino acid digestibility obtained by the apparent and standardized chick excreta and ileal

digestibility and the Conventional Additional Method (CAM) intact and cecectomized adult cockerel assays, two experiments were conducted.

### Experiment 1

**Birds and housing:** The experiments were conducted to determine metabolisable energy and amino acid digestibility content of the soybean, sunflower and canola meals by used a bioassay as collecting ileum digesta and excreta of male broiler chickens. About 200 day-old male broiler chicks (Rose 308) were placed in metabolic cage in environmentally controlled rooms where the initial temperature were 32°C and reduced weekly by 2°C (at an ambient temperature of 21°C and 24-h light), Birds were randomly assigned to each dietary treatment with 6 replicate containing 2 chicks each (12 birds per treatment). The birds received the experimental diets *ad libitum* from 15-21 days of age and from 35-42 days. After the acclimatization period, the birds were given their respective diets *ad libitum* for 4 days and were fasted for 24 h. The birds were then allowed to consume the respective diet for a 3 days period. The birds were again fasted for 24 h. Following this, excreta were collected for 3 time on a tray place under each cage, transferred to frozen (-25°C). Other the killing the birds on days 42 and the contents of the ileum digesta were collected for determine amino acid digestibility and metabolizable energy content of the meals was determined by using Titanium Oxide (TiO<sub>2</sub>) as a marker. Birds were euthanatized 4 h later and the small intestine was immediately exposed. The ileum was tied off, using the vitelline diverticulum as the boundary between jejunum and ileum. Ileal contents were expressed by gentle manipulation and the ileum flushed with distilled water to complete the removal of contents. Because of the small amounts of ileal digesta obtained, samples from three birds were pooled to provide enough material for amino acid and Titanium Dioxide (TiO<sub>2</sub>) analyses and stored at -20°C. Samples, after freeze were ground to pass through a 0.5 mm sieve prior to analysis.

Thus, amino acid content in digesta and excreta were determined in 3 samples per treatment. Feed, ileal digesta and excreta samples submitted to quantify amino acids.

Calculations and statistical analysis. The following equations were used for calculation of metabolizable energy content oil seed meals:

$$\text{AME (kcal)} = [\text{GE}_{\text{kcal/kg diet}} - (\text{TiO}_{2\text{diet}\%} / \text{TiO}_{2\text{excreta}\%} \times \text{GE}_{\text{kcal/kg excreta}})]$$

$$\text{AMEn (kcal)} = \text{AME} - 8.73 [\text{N}_{\text{diet}\%} - (\text{TiO}_{2\text{diet}\%} / \text{TiO}_{2\text{excreta}\%} \times \text{N}_{\text{excreta}\%})]$$

$$\text{TME (kcal)} = \text{AME} + \text{EEL} / I_{\text{ntake}}$$

$$\text{TMEn (kcal)} = \text{AMEn} + [\text{EEL} + (8.73 \times \text{NR}_o) / I_{\text{ntake}}]$$

Where:

GE = Gross energy

N = Nitrogen

TiO<sub>2</sub> = Titanium dioxide

8.73 = The energy equivalent of uric acid nitrogen that is 8.73 kcal kg<sup>-1</sup> of uric acid nitrogen

EEL = Endogenous Energy Losses by the nitrogen free (D glucose) diet fed chickens

RN<sub>0</sub> = (FmEn+UmEn+UeEn)

The substitution, method uses the equation below for calculation of the AME of the test ingredient (oil seed meals) from the AME of the basal diet and the AME of the test diet (oil seed meals) and basal diet.

ME of test ingredient (kcal) = [ME test diet-(ME basal diet×%basal in test diet/100)]/% test ingredient in test diet×100.

**Excreta and ileal digesta processing:** The apparent ileal and excreta amino acid digestibility for each diet contained oil seed meals were calculated by the following equation using titanium TiO<sub>2</sub> as an indigestible marker at a level of 0.3 %:

$$ADAA_{Diet(\%)} \text{ or } DC = 100 - (100 \times [(TiO_{2Diet} \times AA_{Digesta} / TiO_{2Digesta} \times AA_{Diet})])$$

Where:

ADAA<sub>Diet</sub> = Apparent amino acid digestibility of diet or digestibility coefficient

TiO<sub>2Digesta</sub> and TiO<sub>2Diet</sub> = Respective concentrations of TiO<sub>2</sub> in the diet and digesta samples (g kg<sup>-1</sup>)

AA<sub>Digesta</sub> and AA<sub>Diet</sub> = respective concentrations of the AA in the diet and digesta samples (g kg<sup>-1</sup>)

The apparent digestibility of amino acid were transformed to standardized ileal digestibility by correcting for the basal endogenous amino acid losses using the values obtained by nitrogen free diet (D glucose) fed chickens with following formula:

Standardized Ileal digestibility of amino acid (%) = apparent amino acid digestibility(%) + [(endogenous amino acid losses as g/100 g of DM)/(amino acid content of the feedstuffs as g/100 g of DM)×100].

True amino acid digestibility for excreta in broiler of the assay diets was calculated using the following equation.

True amino acid excreta digestibility = AAAD + endogenous amino acid output in excreta×100/amino acid concentration in diet.

The apparent ileal and excreta digestibility of amino acids in oil seed meals were determined by substitution (Woyengo *et al.*, 2010) with the basal diet using the following equation:

$$D_A = D_B + (D_D - D_B)/P_A$$

Where:

D<sub>A</sub> = Digestibility of amino acid in an assay feedstuff (oil seed meal)

D<sub>B</sub> = Digestibility of amino acid in the basal diet

D<sub>D</sub> = Digestibility of amino acid in an assay diet (oil seed meals-basal diet)

P<sub>A</sub> = Proportion (decimal percentage) of assay feedstuffs (oil seed meals) in assay diet

## Experiment 2

**Birds and housing:** The experiment was assay as caecetomised and intact adult cockerels to determine amino acids digestibility and metabolizable energy and also quantities for Soybean (SBM), Canola (CM), Sunflower (SFM) meals. The thirty two (16 intact and 16 caecetomized) adult cockerels (Rhode Island Red type, RIR), (age, 40 weeks; mean body weight, 2.900 kg) were maintained in individual metal cages (0.66 m×0.66 m) with 16 h light/day and free access to feed and water. The average temperature in the experiment house was 24±2°C with a lighting cycle of 16:8 h (light: dark). Each cage was fitted with an individual feeder and a nipple drinker. A fixed aluminium tray was placed under each cage to allow droppings to be collected separately. As well as before experiments, adult cockerels were fed on a diet containing corn (50%), wheat (13%), barley (7.4%), soybean meal (20%) and mineral-vitamin mixture (0.5%). Also before the start of experiment, the birds withheld for 24 h to ensure that no feed residues remained in their alimentary tracts. For the conventional addition method (CAM) method, the experimental period was 6 days: a 3-days pre-collection period and a 3-day collection period. Amount of feed intake during 3 day of experiment period as 118.79-214.17 g per each bird (average 164.86 g). An additional 6 birds were given no feed and served as negative controls to provide a measure of the FEm and UEe (the EEL). The samples of dropping voided during the experiment period were collected, weighted and frozen. Before analysis, the frozen samples were removed from the freezer, taken out of the bags and placed in an oven to be dried at 90°C overnight. Samples of ground maize and excreta were assayed for gross energy by means of an adiabatic oxygen bomb calorimeter.

**Caecetomised adult birds (cockerel):** Caecetomised cockerels were used to overcome the problem of microbial modification of dietary protein and microbial protein synthesis in the hindgut. Caecetomy was performed when cockerels were 38 weeks of age. Prior to surgery, the cockerels selected to undergo the caecetomy were deprived of feed for 24h and water for 24 h. Caecetomy procedure was according with it described by Angkanaporn *et al.* (1997) and Green *et al.* (1987). After the surgery, the birds were kept in a warm (28±2°C) house with *ad libitum* supply of the water and also, solid feed was withheld for 24 h. About 2 weeks after the

operation, the cockerels were used for experiment. Samples were dried at 80°C overnight. Gross energy of the meals and excreta samples were determined by adiabatic oxygen bomb calorimeter using a Parr4 Model 1241 Calorimeter. Crude protein was calculated as total nitrogen $\times$ 6.25, total nitrogen being analyzed by an automated Kjeldahl procedure according to AOAC. (1990) (Association of Analytical Chemists). The collected excreta were dried, weighed and ground to pass a 1-mm screen. For amino acid analysis, the samples were hydrolyzed with 6N HCL and then quantities of amino acids determined by High-Performance Liquid Chromatography (HPLC) according to the procedure described by Siriwan *et al.* (1993) and Moore (2004).

**Calculations and statistical analysis:** The mean value of oil seed meals were determined for each replicated. Total Intake of feed Energy (IE) and Nitrogen (IN) and droppings energy (FE+UE) and nitrogen (FN+UN) were measured for each birds and results from the experiment were evaluated by the following formulae (Yaghoobfar and Boldaji, 2002):

$$\text{AME (Kcal kg}^{-1}\text{ DM)} = [\text{IE} - (\text{FE} + \text{UE})] / \text{FI}$$

$$\text{AMEn (Kcal kg}^{-1}\text{ DM)} = [(\text{IE} - (\text{FE} + \text{UE}) - \text{K} (\text{IN} - (\text{FN} + \text{UN}))) / \text{FI}]$$

$$\text{TME (Kcal kg}^{-1}\text{ DM)} = \text{AME} + \text{EEL} / \text{FI}$$

$$\text{TMEn (Kcal kg}^{-1}\text{ DM)} = \text{AMEn} + (\text{EEL} + (\text{RNo} \times 8.74)) / \text{FI}$$

$$\text{RNo} = (\text{FmEn} + \text{UmEn} + \text{UeEn})$$

Where appropriate, the energy voided in the droppings (FE+UE) was corrected to zero nitrogen balance (FEn+UEn) by assuming that excreta nitrogen, resulting from tissue nitrogen catabolism, has an energy of 8.74 kcal/g (energy value of 1g of urinary nitrogen of tissue origin. Apparent and true fecal digestibilities of amino acids (ADAA and TDAA, respectively) were calculated using these formulas:

$$\text{ADAA (\%)} \text{ or digestibility coefficient} = \left[ \frac{(\text{AA}_c - \text{AA}_e)}{\text{AA}_c} \right] \times 100$$

$$\text{TDAA (\%)} = \left[ \frac{(\text{AA}_c - \text{AA}_e + \text{EAAL})}{\text{AA}_c} \right] \times 100$$

where,  $\text{AA}_c$  (Amino Acid Consumed) = feedstuff intake $\times$  feedstuff amino acid quantity.  $\text{AA}_e$  (Amino acid excreted) = dry excreta weight  $\times$  excreta amino acid quantity, EAAL = Endogenous Amino Acid Losses by fasting cockerel.

### Chemical analysis

**HPLC:** The frozen samples were removed from the freezer and placed in an oven to be dried at 80°C overnight. Gross energy of the meals and excreta samples were determined by adiabatic oxygen bomb calorimeter

using a Parr4 Model 1241 Calorimeter. Crude protein was calculated as total nitrogen $\times$ 6.25, total nitrogen being analyzed by an automated Kjeldahl procedure AOAC 1990 (Association of Analytical Chemists). The collected excreta were dried, weighed and ground to pass a 1 mm screen. For amino acid analysis, the samples were hydrolyzed with 6NHCL and then quantities of amino acids determined by high-performance liquid chromatography (HPLC) according to the procedure described by Siriwan *et al.* (1993) and Moore (2004).

**Statistical analysis:** The experiments were carried out on the basis of a completely randomized design with 4 replicates; Statistical analysis of the data was accomplished using the GLM procedure of SAS software (SAS Institute, 1990) based on completely randomized design with 4 replications. The Duncan's test was used to elucidate differences between treatments means with 0.05 level considered significant.

## RESULTS

The chemical compositions, amino acid concentration and effect of age and bioassay on apparent and true ileal and excreta amino acid digestibility of oilseed meals (soybean meal, canola meal and sunflower meal) evaluated are shown in Table 1-8. The differences between ileal and excreta values from broiler and cockerel (intact and caecectomized) varied depending on the oil meals and the amino acid considered. Among oil meals, average ileal and excreta of broiler and cockerel (intact and caecectomized) amino acid digestibility values

Table 1: Chemical composition (Means $\pm$ SEM) (Percent/DM) and amino acid concentration (g/100 g) in the oilseed meals

| Amino Acid                   | Soybean meal | Sunflower meal | Canola meal |
|------------------------------|--------------|----------------|-------------|
| Dry matter                   | 93.92        | 95.30          | 94.28       |

B1 (excreta digestibility for broiler chickens), B2 (Apparent and standardized ileal digestibility for broiler chickens), B3 (intact cockerel), B4 (caecetomized cockerel) SEM (Standard error of the means)<sup>a-b</sup> Means within row with different superscript are significantly different (p<0.05) Overall mean (Mean of 12 amino acids)

(Table 2) for each bioassay in soybean and sunflower meals were significantly different (p<0.05). In contrast, the digestibility estimates in canola meal were influenced by bioassay, the ileal amino acid digestibility values being

much higher than the corresponding excreta amino acid digestibility values. But for excreta amino acid digestibility in adult bird (intact and Caecetomized) were not significantly different (p>0.05).

Table 5: Apparent and true or standardized amino acid digestibility (%) for canola meals determined in the broiler chickens and adult cockerel

SEM (Standard error of the means)<sup>a-b</sup> Means within row with different superscript are significantly different ( $p < 0.05$ ) Overall mean (Mean of 13 amino acids)

and canola meal 62.05 and 62.45%, respectively. The average cockerels cecectomized apparent and true digestibilities of amino acids in broiler for soybean meal were 80.34, 84.45, sunflower meal 74.48 and 82.47 and canola meal 84.74 and 87.12%, respectively. Proportional differences were present in means of amino acid digestibility between the broiler excreta and ileal with cockerels intact and caeectomized.

The excreta digestibility of amino acid in soybean and canton meals for broiler and cockerel was higher than that for ileum and caeectomized broiler and cockerel respectively. The amino acid digestibility of different age in soybean meal and canola meal (Table 2) for 21 days broiler and adult cockerel was higher than 42 days broiler ( $p < 0.05$ ). However, the average digestibility of amino acids content of sunflower in 42 days broiler was higher than 21 days broiler and cockerel ( $p < 0.05$ ).

The magnitude of the difference between four bioassay values varied greatly depending upon the oil meals and the specific amino acid considered (Table 3 and 5). In contrast, the digestibility estimates in sunflower were influenced by the site of measurements, the excreta amino acid digestibility values being much higher than the corresponding ileum, intact and caeectomized amino acid digestibility values. The average excreta and ileum digestibility of amino acids in soybean, sunflower and canola meals were 79.99, 72.18, 92.16, 48.79, 69.82 and 62.05%, respectively. The corresponding values at the intact and caeectomized birds of soybean sunflower canola meals were 84.18, 80.34, 78.09, 74.28, 86.46 and 84.74%, respectively. However, four bioassay as excreta, ileum, intake and caeectomized were noted for individual amino acids within soybean, sunflower and canola meals. For instance, digestibility of aspartic acid, glutamic acid, valin, lysine in soybean meal ( $p < 0.05$ ). Also, those of aspartic acid, glutamic acid, thyrosin, valine, methionine, leusin and lysine in canola meal ( $p < 0.05$ ) and therefore,

all 12 individual amino acid in sunflower ( $p < 0.05$ ) were influences by the site of measurement. For apparent digestibility of the 12 amino acids compared significant ( $p < 0.05$ ) excreta-ileum and intact and caeectomized differences were found for 7 amino acids in soybean meal, 12 amino acids in sunflower and 7 amino acids in canola meal. Significant difference ( $p < 0.05$ ) in true digestibility, excreta-ileum and intact- caeectomized were recoded for 9 amino acids in soybean, 12 amino acids in sunflower and 7 amino acids in canola meals. Apparent digestibility of amino acid in soybean, sunflower and canola meals measured in broiler bioassay (excreta and ileum) were 9 to 11%, 34-50% and 19 to 27% units lower than those measured at the intact and caeectomized adult cockerel bioassay ( $p < 0.05$ ). The significant differences were particularly evident for aspartic acid (10-11% units, 19-44% units, 14-26% units) glutamic acid (9-7% units, 7-28% units, 16-25% units) valine (11-17% units, 8- 39% units, 42-40% units) lysine (4-16% units, 9-31% units, 19-42% units) in soybean, sunflower and canola meals, respectively. For apparent digestibility of the 12 amino acids compared, significant ( $p < 0.05$ ) excreta-ileum and intact and caeectomized cockerels differences were found for 7 amino acids in soybean meal, 12 in sunflower and 7 amino acids in canola meal. For true digestibility significant ( $p < 0.05$ ) excreta-ileum and intact and caeectomized cockerels differences were recorded for 9 amino acids in soybean, 12 in sunflower and 7 amino acids in canola meal.

The effect of age on the excreta digestibility amino acids in soybean meals are shown in Table 6. The digestibility of amino acid in soybean meal was higher ( $p < 0.05$ ) at 21 age of broiler and adult cockerel compared to those at 42 days age of broiler, except for glysin, tyrosine, valine, methionine cystein, Isoleucine and phenylalanine amino acids. The digestibility of lysine was similar at 21 and 42 days but the digestibility was

significantly higher for adult cockerel ( $p < 0.05$ ). The digestibility of amino acids was higher at 21 and 42 days than those for adult cockerel ( $p < 0.05$ ). The amino acids digestibility in soybean and canola meals for 21 days broiler was higher than 42 days broiler and adult cockerel. However similar trends were not observed for the digestibility of individual amino acid. Aspartic acid, glutamic acid, serine, leucine and lysine increased significantly ( $p < 0.05$ ) for adult cockerel compare to broiler (21 and 42 days). For example lysine varied approximately 11% increasing was observed between broiler and adult cockerels compare. The digestibility of amino acid in sunflower for broiler was significantly ( $p < 0.05$ ) higher than those for adult cockerel (Table 7). The average digestibility of amino acid in broiler was lower than adult cockerel ( $p < 0.05$ ) and the digestibility in broiler at 42 days was lower than those in cockerel and 21 days of broiler ( $p < 0.05$ ). The apparent and true digestibility of amino acids in canola meals at 21 and 42 days of broiler chickens age and adult cockerels shown in Table 8.

The digestibilities of amino acids were similarly higher at 21 days broiler and adult birds than those at 42 days of broiler. Exceptions were serine, glysin, histidine, tyrosine, cystein, isoleucine, phenylalanin and lysine for which no age effect was observed. The digestibility of amino acids in sunflower meal was not influenced by the age of broiler (21 and 42 d) and adult cockerel (Table 7). The digestibility of amino acids was also not influenced by age, except for aspartic acid, serine and phenylalanine.

The digestibility of lysine was similar at the age of 21 and 42 days in broiler and cockerels. However, the digestibility of amino acid were significantly higher ( $p < 0.05$ ) at 21 and 42 days of age of broiler chicken compared to adult cockerel.

The amino acid digestibility in sunflower meals reduced with age from 42 days broiler to adult cockerels. The digestibility of individual amino acid in adult cockerel was higher ( $p < 0.05$ ) than those observed in broiler for soybean and canola meals. The broiler estimated were also lower ( $p < 0.05$ ) than those for cockerel except for sunflower. Digestibility of amino acid was similar between broiler and cockerel, except for glysin, praline, methionine and phenylalanine in soybean and histidine, cystein and phenylalanine in canola meal; which were higher ( $p < 0.05$ ) in cockerel.

The effect of age on metabolizable energy content of oil seed meals (soybean, sunflower and canola meals) are shown in Table 9. The AME and AMEn values obtained for soybean were significantly different between ages ( $p < 0.05$ ). However, AME, AMEn, TME and TMEn values at 42 days of broiler age were significantly lower than those at the 21 days of broiler age ( $p < 0.05$ ). The AME and AMEn values significantly decreased with age for the soybean meals with compare broiler age to adult cockerel but there were no significant effects of age TME

intact cockerels were no differences for MEN, TME and TMEN values of soybean meals. Cecectomy birds had no influence on amount of metabolizable energy values contents of soybean meals.

The results of experiment showed that the excreta and ileum digestibility of broiler did not have any significant effect on metabolizable energy values of canola and sunflower meals. However, intact cockerel experienced higher metabolizable energy from canola and sunflower meals than those broiler excreta and ileum digestibility and cecectomy cockerels ( $p < 0.05$ ). Therefore correction to zero nitrogen and Endogenous Energy Losses (EEL) did not have any effects on values amount of metabolizable energy content of oilseed meals.

Endogenous amino acid excretion values (mg/birds per 48 h) for the fasting (intact and caecectomice) and N-free diet (D (+) glucose) methods (mg kg<sup>-1</sup> DM intake) are shown in Table 11. Mean values were differences in individual amino acid were significant. Endogenous amino acid values for serine, glysin, cystine, isoleucine and phenylalanine were different ( $p < 0.05$ ) between the N-free and fasting methods. The means for the fasting treatment were greater than for the N-free diet treatment for each amino acid except isoleucine. But, endogenous amino acids excretion as cystine and isoleucine in caecectomized birds were significantly higher than Intact by fasting methods.

However, amount of EEL and EAAL obtained of intact and caecectomice bird were not significant differences compare to N-free diet but their result different with each other. Means values of EEL in intact and caecectomice birds were lower than N-free diet but EAAL are higher than N-free diet (Table 12).

## DISCUSSION

In the present study, data had shown that digestibility of amino acids content of soybean and canola meals from intact and caectomized cockerels were higher than those excreta and ileal digestibility of broiler chickens, the reason of this result may be development of physiology and amino acid metabolism by hindgut microflora in adult birds (Parsons *et al.*, 1982).

As well as, the digestibility or coefficient digestibility of amino acid content of sunflower for broiler excreta assay was higher than those other bioassay as intact, caectomized and ileal (standard ileal D), receptively (Kadim *et al.*, 2002; Siriwan *et al.*, 1993). It may be amounts of cell wall carbohydrates that are poorly digestibility in the small intestine. When, fermentable cell wall carbohydrate are limiting the undigested nitrogenous substances will be dominated by the microbes to ammonia and amines resulting in net disappearance of amino acids. Other way, microflora appeared to have only a minor influence on amino acid recovery in the faces (Ten Doeschate *et al.*, 1993).

The amino acid digestibility values of soybean, canola and sunflower meals determined by caecectomized birds were lower than the corresponding determined with intact birds. Our findings are consistent with those of Parson *et al.* (1983) and Johns *et al.* (1986). In these studies clearly demonstrated that amino acids metabolism by hindgut microflora in intact birds and influence amino acid digestibility and due to overestimated or excess values (Parsons *et al.*, 1982).

Differences observed between intact and caecectomized birds noted for the apparent amino acids

digestibility of the 12 amino acid studied in soybean, canola and sunflower meals except cysteine and isoleucine in sunflower meals. These differences become insignificant when apparent digestibility were amended to true or standard digestibilities except for glysin which had significantly higher digestibility in intact birds (87.72) compared to caecetomized birds (72.06) in canola meal and lysine which had higher apparent digestibility in intact than in caecetomized birds. Differences in true digestibility of lysine between intact and caecetomized birds were substantial for three oilseed meals, higher in intact birds compared to caecetomized birds. The general effects of caecetomized observed in the present experiments are consistent with result described for caecetomized birds by various authors (Parsons, 1985; Johns *et al.*, 1986).

This way, intact birds compared to excreta and caecetomized had more result of present study shown that with comparing between four bioassays and age of birds for AME, AMEn, TME and TMEn values contents of three oilseed meals were significantly different (Ragland *et al.*, 1999). In influences on ME values contents of canola and sunflower meals in contrast to soybean meal. But excreta bioassay of broiler chicks had shown higher ME than those ileal, intact and caecetomized birds. Metabolizable energy values obtained of caecetomized birds lower than other bioassays. The differences in ME values associated with age, genetics, sex and environment temperatures and species that may be attributable to variation in the FEm+UEe losses relative to the excreta energy losses of feed origins (Sibbald and Wolynetz, 1985; Yaghubfar, 2001; Yaghubfar and Zahedifar, 2003).

A comparison of age effects on amino acid digestibility of soybean, canola and sunflower meals is of practical importance. For this reason, combined analysis of data for the 3 oilseed meals at three ages was carried out. The results indicated that, in general, the digestibility increased with advancing age of birds. This finding is in agreement with the reports of Wallis and Balnave (1984) and TenDoeschate *et al.* (1993). Digestibility of amino acid in soybean and canola meals was higher at 21 days than 42 days of age. Furthermore, trypsin and chymotrypsin activities in the pancreas have been shown to reach a maximum at day 11 post-hatching and reduce at 23 days (Nitsan and Alumot, 1963). The high intestinal uptake of nutrients in young chicken may be associated closely to their rapid growth rate as well as a larger intestinal surface area per unit weight (Wakita *et al.*, 1970; Uni *et al.*, 1995), thus, young broiler are unable to digest  $\alpha$ -galactoside but digestibility has been shown to increase with age (Carre *et al.*, 1995). On the other hand, digestibility of most amino acids in sunflower was higher

at 42 than at adult cockerels. It is difficult to propose a biological explanation for this unexpected finding (Huang *et al.*, 2005). While some researchers (Zelenka and Liska, 1980; Garcia *et al.*, (2007) have reported lowered digestibility of crude protein and amino acids with advancing age, others (Wallis and Balnave, 1984; TenDoeschate *et al.*, 1993) have found that the digestibility of amino acids increased with age. It would appear that differences in the methodology used might, in part, explain the discrepancy. It is being increasingly recognized that the determination of amino acid digestibility in poultry should be based on the analysis of ileal digesta, because of the modifying and variable effects of caecal microflora (Ravindran *et al.*, 1999).

The differences in apparent amino acid digestibility between intact and caecetomized birds were in endogenous losses (Mirhadi *et al.*, 2009; Kessler, 1981). Differences in the endogenous amino acids output between intact and caecetomized birds have been no constant it may depend on age of birds and environment temperature of experiment because Gereen *et al.* (1987) shown not to be statistically different.

The data indicated that endogenous amino acid excretion using the N-free method was much lower ( $p < 0.05$ ) than that in the fasted birds (intact and caecetomized), except isoleucine that was higher in N-free nitrogen. This result contrast with Song *et al.* (2003) that reported endogenous amino acid excretion using the N-free methods was much higher than that in the fasted birds. Also, Ravindran shown that endogenous flows of amino acid obtained in broiler and rooster were similar except serine and isoleucine in rooster were higher than broiler. But, contrast with Parsons *et al.* (1983) and Muztar and Slinger (1986). Thus, quantities endogenous amino acid excretion by intact and caecetomized adult cockerel were not significant difference. Reporters however, with respect to amino acid excretion from birds fed a protein-free diet vs. fasted control birds are conflictive. Small intestinal and pancreatic secretions contribute the greatest to total endogenous secretions and the principal components of these endogenous secretions are mucoproteins and digestive enzymes which are rich in phenylalanine, glycine, Isoleucine, cystine, serine (Chung and Baker, 1992) and this may entail an error of estimation than gave different results in the determination of true digestibility amino acid in poultry (Ravindran *et al.*, 1999; Song *et al.*, 2003). Thus, in correction using endogenous amino acids determined a different age would clearly result in less accurate true digestibility estimates (Ravindran *et al.*, 2001). Result of experiment, shown that mean value of EEL for the N-free treatment was greater ( $p < 0.05$ ) than for the fasting treatment.

## CONCLUSION

The study confirmed significant differences between ileal and excreta digestibilities and also, for intact and caecectomized cockerels for soybean, canola and sunflower meals. It also showed that AMEn, TME and TMEn values of soybean obtained from excreta digestibility of broiler were significantly higher than ileum digestibility in broiler, intact and caecectomized digestibility in cockerels. Therefore, intact cockerels experienced higher metabolizable energy from canola and sunflower meals than those excreta and ileum digestibility or caecectomized cockerels. The data show that endogenous amino acid excretion obtained of the N-free method was lower than the fasted birds as intact and caecectomized but amount of Endogenous Energy Losses (EEL) was greater.
